# Computing correctly rounded logarithms with fixed-point operations

#### Julien Le Maire, Florent de Dinechin and Jean-Michel Muller

## Outline

#### Introduction and context

The Table Maker's dilemma

One algorithm, many variants

#### Results

Bonus: a floating-point in, fixed-point out variant

#### Conclusions

# Preparing 2017, international year of the logarithm

John Napier (aka Neper), 1550-1617

• popularized the use of the point in decimal notation

# Preparing 2017, international year of the logarithm

John Napier (aka Neper), 1550-1617

- popularized the use of the point in decimal notation
- Mirifici Logarithmorum Canonis Descriptio (1614)

# Preparing 2017, international year of the logarithm

John Napier (aka Neper), 1550-1617

- popularized the use of the point in decimal notation
- Mirifici Logarithmorum Canonis Descriptio (1614)

Celebrate a very specific year:

- 400th anniversary of Napier's death
- 6th logarithmic anniversary of the 1614 publication
- ... with three amazing presentations this morning,

now doubt they will trigger many others.

### This talk is also about hardware and C

### This talk is also about hardware and C

## This talk is also about hardware and C

#### An experiment

Implementing the *floating-point* logarithm function

- using only *integer* arithmetic
- for *performance*

(previous work motivated by *lack of FP hardware*)

- 64-bit floating-point, but only 52-bit precision
  - if you can predict the value of the exponent, exponent bits are wasted bits.

- 64-bit floating-point, but only 52-bit precision
  - if you can predict the value of the exponent, exponent bits are wasted bits.

(mulq)

- modern 64-bit machines offer all sort of useful integer instructions
  - addition
  - multiplication  $64 \times 64 \rightarrow 128$
  - count leading zeroes, shifts (*lzcnt, bsr*)

- 64-bit floating-point, but only 52-bit precision
  - if you can predict the value of the exponent, exponent bits are wasted bits.
- modern 64-bit machines offer all sort of useful integer instructions
  - addition
  - multiplication  $64 \times 64 \rightarrow 128$  (mulq)
  - count leading zeroes, shifts (*lzcnt, bsr*)
- most operations are faster on integers, especially addition (which more or less defines the processor cycle time)

- 64-bit floating-point, but only 52-bit precision
  - if you can predict the value of the exponent, exponent bits are wasted bits.
- modern 64-bit machines offer all sort of useful integer instructions
  - addition
  - multiplication  $64 \times 64 \rightarrow 128$  (mulq)
  - count leading zeroes, shifts (*lzcnt, bsr*)
- most operations are faster on integers, especially addition (which more or less defines the processor cycle time)
- small multiprecision out of the box:

mainstream compilers (gcc, clang, icc) support int\_128

- addition  $128 \times 128 \rightarrow 128$  (add, adc)
- shift on two registers (shld, shrd)

- 64-bit floating-point, but only 52-bit precision
  - if you can predict the value of the exponent, exponent bits are wasted bits.
- modern 64-bit machines offer all sort of useful integer instructions
  - addition
  - multiplication  $64 \times 64 \rightarrow 128$  (mulq)
  - count leading zeroes, shifts (*lzcnt, bsr*)
- most operations are faster on integers, especially addition (which more or less defines the processor cycle time)
- small multiprecision out of the box:

mainstream compilers (gcc, clang, icc) support int\_128

- addition  $128 \times 128 \rightarrow 128$  (add, adc)
- shift on two registers (*shld*, *shrd*)

Caveat: integer SIMD/vector support still lagging behind FP (no vector multiplication)

•  $\ln(a \times b) = \ln(a) + \ln(b)$ 

• 
$$\ln (a \times b) = \ln (a) + \ln (b)$$
  
•  $\ln (b^{a}) = a \times \ln(b)$   
• Taylor: for x small,  $\ln(1 + x) \approx x - x^{2}/2 + x^{3}/3...$   
y  
y  
y  
y  
y  
ln(x)  
y  
-1  
-2  
-2

### Logarithm, the floating-point version

The natural logarithm is called log

(you will also find log2 and log10 and a few others)

- Range:  $\forall x \in \mathbb{F}_{64}$   $\log(x) \in [-745, 710]$ 
  - looks like a waste of exponent bits...

## Logarithm, the floating-point version

The natural logarithm is called log

(you will also find log2 and log10 and a few others)

• Range:  $\forall x \in \mathbb{F}_{64}$   $\log(x) \in [-745, 710]$ 

looks like a waste of exponent bits...

- Rounding
  - Recommended:  $\forall x \in \mathbb{F}_{64}$   $\log(x) = \circ(\ln(x))$
  - In practice: implementing this definition difficult and expensive, due to the Table Maker's dilemma.

## Outline

#### Introduction and context

#### The Table Maker's dilemma

One algorithm, many variants

#### Results

- I want 12 significant digits
- I have an approximation scheme that provides 14 digits
  - $y = \log(x) \pm 10^{-14}$
- "Usually" that's enough to round

 $y = x, xxxxxxxx17 \pm 10^{-14}$ 

$$y = x, xxxxxxxx83 \pm 10^{-14}$$

Dilemma when

$$y = x, xxxxxxxx50 \pm 10^{-14}$$

The first table-makers rounded these cases randomly,

and recorded them to confound copiers.

#### $y = x, xxxxxxx50 \pm 10^{-14}$ Difficult to round

 $y = x, xxxxxxx4996 \pm 10^{-16}$ Computing more accurately solves it

- $\forall x \in \mathbb{F}, \ln(x)$  is transcendental
- There is a finite number  $(2^{64})$  of floating-point numbers.

- $\forall x \in \mathbb{F}, \ln(x)$  is transcendental
- There is a finite number  $(2^{64})$  of floating-point numbers.
- One of them is the worst to round

(and it is more expensive to compute)
## Solving the Table Maker's dilemma

- $\forall x \in \mathbb{F}, \ln(x)$  is transcendental
- There is a finite number (2<sup>64</sup>) of floating-point numbers.
- One of them is the worst to round
- Muller and Lefèvre computed that it requires an accuracy of 2<sup>-113</sup>: evaluating the log to this accuracy enables correct rounding
- but we don't need this accuracy for most cases

(and it is more expensive to compute)

#### On-demand accuracy

CRLibm refinement of Ziv's technique:

- First step: quick-and-dirty evaluation of ln(x) (just accurate enough to ensure correct rounding in most cases)
- test if rounding can be decided
- if not (rarely), recompute ln(x) with the worst-case accuracy

#### **On-demand accuracy**

CRLibm refinement of Ziv's technique:

- First step: quick-and-dirty evaluation of ln(x) (just accurate enough to ensure correct rounding in most cases)
- test if rounding can be decided
- if not (rarely), recompute ln(x) with the worst-case accuracy

Trade-off between first and second steps:

*MeanTime* = *Time*(1st step) + Pr[need 2nd step] · *Time*(2nd step)

#### **On-demand accuracy**

CRLibm refinement of Ziv's technique:

- First step: quick-and-dirty evaluation of ln(x) (just accurate enough to ensure correct rounding in most cases)
- test if rounding can be decided
- if not (rarely), recompute ln(x) with the worst-case accuracy

Trade-off between first and second steps:

*MeanTime* = *Time*(1st step) + Pr[need 2nd step] · *Time*(2nd step)

Best so far:  $Time(2nd \ step) \approx 10 \times Time(1st \ step)$ In this work we improve this to a factor 2.

## Outline

Introduction and context

The Table Maker's dilemma

One algorithm, many variants

Results

Bonus: a floating-point in, fixed-point out variant

Conclusions

# The big picture

- 1. Filter special cases (negative numbers,  $\infty$ , ...)
- 2. Argument range reduction
- 3. Polynomial approximation
- 4. Solution reconstruction
- 5. Error evaluation and rounding test
- 6. If more accuracy needed:

Rerun the steps 3 and 4 with the worst-case accuracy.

## IEEE 754 floating-point

Value represented:

$$(-1)^s \cdot 2^E \cdot (1+x)$$

## IEEE 754 floating-point

Value represented:

$$(-1)^s \cdot 2^E \cdot (1+x)$$

Special cases  $(\pm\infty,0,\textit{NaN})$  encoded in special values of the exponent field

#### Special cases: businesss as usual

```
/* reinterpret x to manipulate its bits more easily */
uint64_t xbits = ((union { double d; uint64_t u; }){x}).u;
 int xe = xbits >> 52;
 /* filter the special cases: !(x is normalized and 0 < x < +1nf) *
 if (0x7FEu <= (unsigned)xe - 1u) {
   /* x = + 0: raise a DivideByzero, return - Inf */
   if ((xbits \& ~(1ull << 63)) == 0) return -1.0/0.0;
   /* x < 0.0: raise a InvalidOperation , return a qNaN */
    if ((xbits \& (1ull << 63)) != 0) return (x-x)/0;
    /* x = qNaN: return a qNaN
x = sNaN: raise a InvalidOperation, return a qNaN
      x = +Inf: return +Inf */
   if (xe != 0) return x+x;
    /* x subnormal: change x to a normalized number */
    else {
        int u = clz64(xbits) - 12;
        xbits <<= u + 1:
       xe -= u;
    }
```

## First argument range reduction

$$input = 2^{E} \cdot (1+x)$$
$$ln(input) = E \cdot ln(2) + ln(1+x)$$

## First argument range reduction

$$input = 2^{E} \cdot (1 + x)$$
$$ln(input) = E \cdot ln(2) + ln(1 + x)$$

Evaluation algorithm:

• approximate  $\ln(1+x)$  with a polynomial p(x)

degree needed: at least 26

- evaluate  $E \cdot \ln(2)$
- add both terms

# Tang's range reduction

• A table, addressed by the  $x_1$  most significand bits of x, stores  $inv_x \approx \frac{1}{1+x}$  and  $\ln(inv_x)$ 

# Tang's range reduction

• A table, addressed by the x<sub>1</sub> most significand bits of x, stores

• As 
$$inv_x \approx \frac{1}{1+x}$$
 and  $ln(inv_x)$   
• As  $inv_x \cdot (1+x) \approx 1$ , define  
 $inv_x \cdot (1+x) = 1+y$ 

# Tang's range reduction

• A table, addressed by the x<sub>1</sub> most significand bits of x, stores

$$inv_x \approx \frac{1}{1+x}$$
 and  $ln(inv_x)$   
• As  $inv_x \cdot (1+x) \approx 1$ , define  
 $inv_x \cdot (1+x) = 1+y$ 

• Then

$$\ln(1+x) = \ln(1+y) - \ln(inv_x)$$

J. Le Maire, F. de Dinechin and J.-M. Muller Co

Computing correctly rounded logarithm with fixed-point operations

## Tang's range reduction algorithm

- Extract the index x<sub>1</sub>
- Read, from a table addressed by  $x_1$ , both  $inv_x$  and  $ln(inv_x)$
- compute  $y = inv_x \cdot (1+x) 1$  (exactly)
- approximate  $\ln(1+y)$  with a polynomial p(y)

Degree needed: 8

add it all:

 $\ln(input) \approx E \cdot \ln(2) + p(y) - \ln(inv_x)$ 

## Here integers are better than floating-point

With a 53-bit 1 + x we can tabulate *inv*<sub>x</sub> on 18 bits:

- the exact product would need 71 bits
- but we can predict the 7 leading bits
- $\bullet$  ... so we can let them overflow quietly and use a  $64\times 64 \to 64$  multiplication.

# Random remark about floating-point implementations of Tang's reduction

- There are reciprocal approximation instructions in most recent processors, including this pentium.
- Computing y = inv<sub>x</sub> ⋅ (1 + x) − 1 exactly requires an FMA, or double-extended, or a bit of double-FP arithmetic

## Two levels of Tang reduction

 $\begin{array}{l} x \in [0,1) \\ y \in \left[0,2^{-5.41503}\right) \\ z \in \left[0,2^{-11.8262}\right) \end{array} \begin{array}{c} x_1 \ takes \ 64 \ different \ values \\ y_1 \ takes \ 96 \ different \ values \\ y_2 \ takes \ 96 \ different \ values \\ y_1 \ takes \ 96 \ different \ values \\ y_2 \ takes \ 96 \ different \ values \\ y_2 \ takes \ 96 \ different \ values \\ y_3 \ takes \ 96 \ different \ values \\ y_4 \ takes \ 96 \ different \ values \\ y_5 \ takes \ 96 \ different \ values \\ y_6 \ takes \ 96 \ different \ values \\ y_6 \ takes \ 96 \ different \ values \\ y_6 \ takes \ 96 \ different \ values \\ y_6 \ takes \ 96 \ different \ values \\ y_6 \ takes \ 96 \ different \ values \\ y_6 \ takes \ 96 \ different \ values \\ y_6 \ takes \ 96 \ different \ values \\ y_6 \ takes \ 96 \ different \ values \\ y_6 \ takes \ 96 \ different \ values \\ y_6 \ takes \ 96 \ different \ values \\ y_6 \ takes \ 96 \ different \ values \\ y_6 \ takes \ 96 \ different \ values \\ y_6 \ takes \ 96 \ different \ values \\ y_6 \ takes \ 96 \ different \ values \\ y_6 \ takes \ 96 \ takes$ 

## Ugly code 2: 2 levels of Tang's reduction

#### Why stop at two levels of reduction?

Answer is: diminushing return.

For a target accuracy of  $2^{-60}$ :

	interval of x	degree needed
No reduction	[-1/2, 1/2]	29
1 level	$[-2^{-7}, 2^{-7}]$	7
2 levels	$[-2^{-12}, 2^{-12}]$	4
3 levels	$[-2^{-18}, 2^{-18}]$	3

Adding more levels will cost more operations than it saves...

#### Parenthesis: hardware-oriented algorithms

I have been strongly encouraged to Alt-Tab to other irrelevant slides...

Arith 2007 "Return of the hardware elementary function"

- Iterate on the same range reduction
- Stop as soon as Taylor at order 2 is good enough:  $p(z) = z - z^2/2$  because it is very easy to compute
- Build ad-hoc rectangular multipliers
- No need to tabulate  $1/(1 + x_i)$  when  $x_i$  is small enough.

# Polynomial approximation (advertisement)

Back to our business.

We want to approximate log(1 + z) on an interval around 0. Use the (now standard) tool set to obtain it.

- Sollya:
  - finds a machine-efficient polynomial P(z)
  - computes a safe bound on the approximation error  $P(z) \ln(1+z)$
- Gappa: bounds the accumulation of rounding errors

when evaluating P(z) in C

We obtain a Coq proof of the error:

#### Fixed-point means: explicit shifts

Note that some of the shifts are inside the constants

input = 
$$2^e \cdot (1+x)$$

$$input = 2^e \cdot \frac{1}{inv_x} \cdot (1+y)$$

$$input = 2^{e} \cdot \frac{1}{inv_{x}} \cdot \frac{1}{inv_{y}} \cdot (1+z)$$

$$input = 2^{e} \cdot \frac{1}{inv_{x}} \cdot \frac{1}{inv_{y}} \cdot (1+z)$$
  
$$\ln(input) = e \cdot \ln(2) + \ln(inv_{x}^{-1}) + \ln(inv_{y}^{-1}) + \ln(1+z)$$

$$input = 2^{e} \cdot \frac{1}{inv_{x}} \cdot \frac{1}{inv_{y}} \cdot (1+z)$$

$$ln(input) = e \cdot ln(2) + ln(inv_{x}^{-1}) + ln(inv_{y}^{-1}) + ln(1+z)$$

$$e \cdot ln(2):$$

$$ln(inv_{x}^{-1}):$$

$$ln(inv_{y}^{-1}):$$

$$P(z) \approx ln(1+z):$$
sum:
$$1 = 0$$

$$-53 = -117$$

"If we can predict the exponents, exponent bits are wasted bits"

J. Le Maire, F. de Dinechin and J.-M. Muller Computing correctly rounded logarithm with fixed-point operations

$$input = 2^{e} \cdot \frac{1}{inv_{x}} \cdot \frac{1}{inv_{y}} \cdot (1+z)$$

$$ln(input) = e \cdot ln(2) + ln(inv_{x}^{-1}) + ln(inv_{y}^{-1}) + ln(1+z)$$

$$e \cdot ln(2):$$

$$ln(inv_{x}^{-1}):$$

$$ln(inv_{y}^{-1}):$$

$$P(z) \approx ln(1+z):$$
sum:

"If we can predict the exponents, exponent bits are wasted bits"

$$input = 2^{e} \cdot \frac{1}{inv_{x}} \cdot \frac{1}{inv_{y}} \cdot (1+z)$$
$$\ln(input) = e \cdot \ln(2) + \ln(inv_{x}^{-1}) + \ln(inv_{y}^{-1}) + \ln(1+z)$$

"If we can predict the exponents, exponent bits are wasted bits"

$$input = 2^{e} \cdot \frac{1}{inv_{x}} \cdot \frac{1}{inv_{y}} \cdot (1+z)$$
$$\ln(input) = e \cdot \ln(2) + \ln(inv_{x}^{-1}) + \ln(inv_{y}^{-1}) + \ln(1+z)$$

"If we can predict the exponents, exponent bits are wasted bits"

#### Now it really gets ugly

```
/* Compute part of the result that don't depend on Z
  (xe*log(2) + log(1/Ri) + log(1/Si)) */
uint128_t cstpart =
  fullimul(xe, log2fw_mid)
  + UINT128((int64_t)xe * log2fw_high, 0) // no full mul here

               + UINT128(argReduc1[ri].log_hi, argReduc1[ri].log_mid)
                + UINT128(argReduc2[si].log_hi, argReduc2[si].log_mid);
/* Assemble the two parts, compute the sign, mantissa and exponent
uint128_t longres = cstpart + (zpzpart >> (11 + IMPLICIT_ZEROS));
uint64_t sign = - (HI(longres) >> 63); // sign is 0 if result >
// if sign != 0, this is longres = ~ longres: it approximate the a
// to avoid the approximation, do: longres = ((int64_t)sign + long
longres ^= UINT128(sign, sign);
int u = clz64(HI(longres)) + 1;
int exponent = 11 - u;
uint64_t mantissa = HI(longres << u);</pre>
```

 $\epsilon < (|e|) \cdot 2^{-117}$ 

 $\epsilon < (|e| + 1 + 1) \cdot 2^{-117}$ 

#### Rounding test

Simple technique: compute the two bounds of the interval, and see if they round to the same mantissa

(two additions, a xor and a shift)

#### Rounding test

Simple technique: compute the two bounds of the interval, and see if they round to the same mantissa

(two additions, a xor and a shift)

#### Rounding test

Simple technique: compute the two bounds of the interval, and see if they round to the same mantissa

(two additions, a xor and a shift)

For comparison, the proof of the floating-point-based rounding test (invented by Ziv and used in CRLibm) is an 18-page paper that took 20 years to publish...

#### Error evaluation and rounding test

```
/* Assemble the computed result */
uint64_t resultbits = ((uint64_t)sign << 63)
+ ((uint64_t)(exponent+1023) << 52)
+ (mantissa >> 12)
+ ((mantissa >> 11) & 1); /* round to nearest */
return (union { uint64_t u; double d; }){ resultbits }.d;
```

#### Second step

- Use 3 words instead of 2 for the precomputed log
- Use a much more accurate polynomial:
  - with coefficients on 128 bits instead of 64 (but z is still only a 64-bit number)
  - and using a higher degree polynomial

# Outline

Introduction and context

The Table Maker's dilemma

One algorithm, many variants

#### Results

Bonus: a floating-point in, fixed-point out variant

Conclusions

## A few Pareto points in the design space

Table size (bytes)	degree 1st	degree 2nd
39,936	3	5
12,288	3	6
4,032	4	7
2,240	4	8
2,016	4	9
900	5	10
594	6	12
298	7	14

# Implementation parameters of correctly rounded implementations

	glibc	crlibm-td	crlibm-de	cr-FixP
degree pol. 1	3/8	6	7	4
degree pol. 2	20	12	14	7
tables size	13 Kb	8192 bytes	6144 bytes	4032 bytes
% accurate phase	N/A	1.5	0.4	4.4

#### Pentium timing

cycles	MKL	glibc	crlibm	cr-de	cr-FixP
avg time	25	90	69	46	49
max time	25	11,554	642	410	79

#### Timing breakdown on two processors

cycles	Core i5	Bostan
System	glibc	newlib
	90	105
quick phase alone	42	94
accurate phase alone	74	181
both phases (avg time)	49	121
both phases (max time)	79	225

#### Slanted means: no correct rounding

- Improvement in the range reduction thanks to a wider format
- ... leading to improvements in polynomial degree and table size
- Improvement in the rounding test
- Improvement in the worst-case evaluation time
- Probability to launch 2nd step is high,

but this is acceptable since 2nd step is so cheap

• A branchless correctly rounded variant that is better than the glibc

# Outline

Introduction and context

The Table Maker's dilemma

One algorithm, many variants

Results

Bonus: a floating-point in, fixed-point out variant

Conclusions

# Motivation

TKF91 : DNA sequence alignment algorithm

• dynamic programming algorithm:

alignment as a path within a 2D array.

- borders of an array initialized with log-likelihoods
- then array filled using recurrence formulae
   that involve only may an

that involve only max and + operations.

All current implementations of this algorithm use a floating-point array, but

- int64 + and max are 1-cycle, vectorizable, and exact operations;
- absolute accuracy of initialization logs: up to  $2^{-42}$  with FP log,  $2^{-52}$  with FixP log.

## Floating-point in, fixed-point out

• output: fixed-point, 12 bits integer part, 52 bit fractional part

integer part

fraction

• faithful: target absolute accuracy  $2^{-52}$ 

output format	absolute accuracy	table size	Core i5 cycles	Bostan cycles
Fix64	2 <sup>-52</sup>	2304	24	66
Fix128	2 <sup>-116</sup>	4032	60	179
double (libm)	2 <sup>-42</sup>		90	105

• Fix64 is the code of the first step only,

without the conversion to float.

 $\bullet$  tweak: poly degree 3 only for abs. accuracy  $2^{-59}$ 

• Fix128 is the code of the second step only, without the conversion to float.

# Only partial experiments

- Improvement in accuracy measured
- No noticeable improvement in performance

# Outline

Introduction and context

The Table Maker's dilemma

One algorithm, many variants

Results

Bonus: a floating-point in, fixed-point out variant

Conclusions

# Conclusion

- Competitive against state-of-the-art
- 2nd step faster than other implementations
- Possible to do only the second step
- Better argument reduction

Limitations:

# Conclusion

- Competitive against state-of-the-art
- 2nd step faster than other implementations
- Possible to do only the second step
- Better argument reduction

Limitations:

- Less portable than floating-point
- No support for vectorization

# Conclusion

- Competitive against state-of-the-art
- 2nd step faster than other implementations
- Possible to do only the second step
- Better argument reduction

Limitations:

- Less portable than floating-point
- No support for vectorization
- Minimize latency, not throughput

#### Future work

#### Going further with the logarithm

- Computing the worst-cases for absolute precision
- Finishing the Gappa proof (solution reconstruction)
- Trying variant without the cancellations
- Implementing the log in Metalibm
- Comparing with the log already in *Metalibm*, or on other platforms
